Abstract

Many integrable hierarchies of differential equations allow a variational description, called a Lagrangian multiform or a pluri-Lagrangian structure. The fundamental object in this theory is not a Lagrange function but a differential $d$-form that is integrated over arbitrary $d$-dimensional submanifolds. All such action integrals must be stationary for a field to be a solution to the pluri-Lagrangian problem. In this paper we present a procedure to obtain Hamiltonian structures from the pluri-Lagrangian formulation of an integrable hierarchy of PDEs. As a prelude, we review a similar procedure for integrable ODEs. We show that the exterior derivative of the Lagrangian $d$-form is closely related to the Poisson brackets between the corresponding Hamilton functions. In the ODE (Lagrangian 1-form) case we discuss as examples the Toda hierarchy and the Kepler problem. As examples for the PDE (Lagrangian 2-form) case we present the potential and Schwarzian Korteweg-de Vries hierarchies, as well as the Boussinesq hierarchy.

1 Introduction

Some of the most powerful descriptions of integrable systems use the Hamiltonian formalism. In mechanics, Liouville-Arnold integrability means having as many independent Hamilton functions as the system has degrees of freedom, such that the Poisson bracket of any two of them vanishes. In the case of integrable PDEs, which have infinitely many degrees of freedom, integrability is often defined as having an infinite number of commuting Hamiltonian flows, where again each two Hamilton functions have a zero Poisson bracket. In addition, many integrable PDEs have two compatible Poisson brackets. Such a bi-Hamiltonian structure can be used to obtain a recursion operator, which in turn is an effective way to construct an integrable hierarchy of PDEs.

In many cases, especially in mechanics, Hamiltonian systems have an equivalent Lagrangian description. This raises the question whether integrability can be described from a variational perspective too. Indeed, a Lagrangian theory of integrable hierarchies has been developed over the last decade or so, originating in the theory of integrable lattice
Hamiltonian structures for hierarchies of Lagrangian PDEs

equations (see for example [14], [3], [12, Chapter 12]). It is called the theory of Lagrangian multiform systems, or, of pluri-Lagrangian systems. The continuous version of this theory, i.e. its application to differential equations, was developed among others in [26, 28]. Recently, connections have been established between pluri-Lagrangian systems and variational symmetries [18, 19, 22] as well as Lax pairs [21].

Already in one of the earliest studies of continuous pluri-Lagrangian structures [26], the pluri-Lagrangian principle for ODEs was shown to be equivalent to the existence of commuting Hamiltonian flows (see also [24]). In addition, the property that Hamilton functions are in involution can be expressed in Lagrangian terms as closedness of the Lagrangian form. The main goal of this work is to generalize this connection between pluri-Lagrangian and Hamiltonian structures to the case of integrable PDEs.

A complementary approach to connecting pluri-Lagrangian structures to Hamiltonian structures was recently taken in [6]. There, a generalisation of covariant Hamiltonian field theory is proposed, under the name Hamiltonian multiform, as the Hamiltonian counterpart of Lagrangian multiform systems. This yields a Hamiltonian framework where all independent variables are on the same footing. In the present work we obtain classical Hamiltonian structures where one of the independent variables is singled out as the common space variable of all equations in a hierarchy.

We begin this paper with an introduction to pluri-Lagrangian systems in Section 2. The exposition there relies mostly on examples, while proofs of the main theorems can be found in Appendix A. Then we discuss how pluri-Lagrangian systems generate Hamiltonian structures, using symplectic forms in configuration space. In Section 3 we review this for ODEs (Lagrangian 1-form systems) and in Section 4 we present the case of (1 + 1)-dimensional PDEs (Lagrangian 2-form systems). In each section, we illustrate the results by examples.

2 Pluri-Lagrangian systems

A hierarchy of commuting differential equations can be embedded in a higher-dimensional space of independent variables, where each equation has its own time variable. All equations share the same space variables (if any) and have the same configuration manifold $Q$. We use coordinates $t_1, t_2, \ldots, t_N$ in the multi-time $M = \mathbb{R}^N$. In the case of a hierarchy of (1 + 1)-dimensional PDEs, the first of these coordinates is a common space coordinate, $t_1 = x$, and we assume that for each $i \geq 2$ there is a PDE in the hierarchy expressing the $t_i$-derivative of a field $u : M \to Q$ in terms of $u$ and its $x$-derivatives. Then the field $u$ is determined on the whole multi-time $M$ if initial values are prescribed on the $x$-axis. In the case of ODEs, we assume that there is a differential equation for each of the time directions. Then initial conditions at one point in multi-time suffice to determine a solution.

We view a field $u : M \to Q$ as a smooth section of the trivial bundle $M \times Q$, which has coordinates $(t_1, \ldots, t_N, u)$. The extension of this bundle containing all partial derivatives of $u$ is called the infinite jet bundle and denoted by $M \times J^\infty$. Given a field $u$, we call the corresponding section $[u] = (u, u_t, u_{tt}, \ldots)$ of the infinite jet bundle the infinite jet prolongation of $u$. (See e.g. [1] or [17, Sec. 3.5].)

In the pluri-Lagrangian context, the Lagrange function is replaced by a jet-dependent
d-form. More precisely we consider a fiber-preserving map
\[ \mathcal{L} : M \times J^\infty \to \bigwedge^d (T^*M) \].
Since a field \( u : M \to Q \) defines a section of the infinite jet bundle, \( \mathcal{L} \) associates to it a section of \( \bigwedge^d (T^*M) \), that is, a d-form \( \mathcal{L}[u] \). We use the square brackets \([u]\) to denote dependence on the infinite jet prolongation of \( u \). We take \( d = 1 \) if we are dealing with ODEs and \( d = 2 \) if we are dealing with \((1 + 1)\)-dimensional PDEs. Higher-dimensional PDEs would correspond to \( d > 2 \), but are not considered in the present work. (An example of a Lagrangian 3-form system, the KP hierarchy, can be found in [22].) We write
\[ \mathcal{L}[u] = \sum_i \mathcal{L}_i[u] \, dt_i \]
for 1-forms and
\[ \mathcal{L}[u] = \sum_{i,j} \mathcal{L}_{ij}[u] \, dt_i \wedge dt_j \]
for 2-forms.

**Definition 2.1.** A field \( u : M \to Q \) is a solution to the pluri-Lagrangian problem for the jet-dependent d-form \( \mathcal{L} \), if for every d-dimensional submanifold \( \Gamma \subset M \) the action \( \int_\Gamma \mathcal{L}[u] \) is critical with respect to variations of the field \( u \), i.e.
\[ \frac{d}{d\varepsilon} \int_\Gamma \mathcal{L}[u + \varepsilon v] \bigg|_{\varepsilon=0} = 0 \]
for all variations \( v : M \to Q \) such that \( v \) and all its partial derivatives are zero on \( \partial\Gamma \).

Some authors include in the definition that the Lagrangian d-form must be closed when evaluated on solutions. That is equivalent to requiring that the action is not just critical on every d-submanifold, but also takes the same value on every d-submanifold (with the same boundary and topology). In this perspective, one can take variations of the submanifold \( \Gamma \) as well as of the fields. We choose not to include the closedness in our definition, because slightly weaker property can be obtained as a consequence Definition 2.1 (see Proposition A.2 in the Appendix). Most of the authors that include closedness in the definition use the term “Lagrangian multiform” (e.g. [11, 12, 32, 33, 22]), whereas those that do not tend to use “pluri-Lagrangian” (e.g. [4, 5, 27]). Whether or not it is included in the definition, closedness of the Lagrangian d-form is an important property. As we will see in Sections 3.4 and 4.4, it is the Lagrangian counterpart to vanishing Poisson brackets between Hamilton functions.

Clearly the pluri-Lagrangian principle is stronger than the usual variational principle for the individual coefficients \( \mathcal{L}_i \) or \( \mathcal{L}_{ij} \) of the Lagrangian form. Hence the classical Euler-Lagrange equations are only a part of the system equations characterizing a solution to the pluri-Lagrangian problem. This system, which we call the multi-time Euler-Lagrange equations, was derived in [28] for Lagrangian 1- and 2-forms by approximating an arbitrary given curve or surface \( \Gamma \) by stepped curves or surfaces, which are piecewise flat with tangent spaces spanned by coordinate directions. In Appendix A we give a more intrinsic proof
that the multi-time Euler-Lagrange equations imply criticality in the pluri-Lagrangian sense. Yet another proof can be found in [23].

In order to write the multi-time Euler-Lagrange equations in a convenient form, we will use the multi-index notation for (mixed) partial derivatives. Let $I$ be an $N$-index, i.e. a $N$-tuple of non-negative integers. We denote by $u_I$ the mixed partial derivative of $u : \mathbb{R}^N \to Q$, where the number of derivatives with respect to each $t_i$ is given by the entries of $I$. Note that if $I = (0, \ldots, 0)$, then $u_I = u$. We will often denote a multi-index suggestively by a string of $t_i$-variables, but it should be noted that this representation is not always unique. For example,

$$t_1 = (1,0,\ldots,0), \quad t_N = (0,\ldots,0,1), \quad t_1 t_2 = t_2 t_1 = (1,1,0,\ldots,0).$$

In this notation we will also make use of exponents to compactify the expressions, for example

$$t_2^3 = t_2 t_2 t_2 = (0,3,0,\ldots,0).$$

The notation $I t_j$ should be interpreted as concatenation in the string representation, hence it denotes the multi-index obtained from $I$ by increasing the $j$-th entry by one. Finally, if the $j$-th entry of $I$ is nonzero we say that $I$ contains $t_j$, and write $I \ni t_j$.

### 2.1 Lagrangian 1-forms

**Theorem 2.2** ([28]). Consider the Lagrangian 1-form

$$\mathcal{L}[u] = \sum_{j=1}^{N} \mathcal{L}_j[u] \, dt_j,$$

depending on an arbitrary number of derivatives of $u$. A field $u$ is critical in the pluri-Lagrangian sense if and only if it satisfies the multi-time Euler-Lagrange equations

$$\frac{\delta_j \mathcal{L}_j}{\delta u_I} = 0 \quad \forall I \not\ni t_j, \quad (1)$$

$$\frac{\delta_j \mathcal{L}_j}{\delta u_{It_j}} - \frac{\delta_1 \mathcal{L}_1}{\delta u_{It_1}} = 0 \quad \forall I, \quad (2)$$

for all indices $j \in \{1, \ldots, N\}$, where $\frac{\delta_j}{\delta u_I}$ denotes the variational derivative in the direction of $t_j$ with respect to $u_I$,

$$\frac{\delta_j}{\delta u_I} = \frac{\partial}{\partial u_I} - \frac{\partial_j}{\partial u_{It_j}} + \frac{\partial^2_j}{\partial u_{It_j t_j}} - \cdots,$$

and $\partial_j = \frac{d}{dt_j}$.

Note the derivative $\partial_j$ equals the total derivative $\sum_I u_{It_j} \frac{\partial}{\partial u_I}$ if it is applied to a function $f[u]$ that only depends on $t_j$ through $u$. Using the total derivative has the advantage that calculations can be done on an algebraic level, where the $u_I$ are formal symbols that do not necessarily have an analytic interpretation as a derivative.
Example 2.3. The Toda lattice describes $N$ particles on a line with an exponential nearest-neighbor interaction. We denote the displacement from equilibrium of the particles by $u = (q^{[1]}, \ldots, q^{[N]})$. We impose either periodic boundary conditions (formally $q^{[0]} = q^{[N]}$ and $q^{[N+1]} = q^{[1]}$) or open-ended boundary conditions (formally $q^{[0]} = \infty$ and $q^{[N+1]} = -\infty$). We will use $q^{[k]}_j$ as shorthand notation for the derivative $\frac{dq^{[k]}_j}{dt}$. Consider the hierarchy consisting of the Newtonian equation for the Toda lattice,

$$q^{[k]}_{1t} = \exp(q^{[k+1]} - q^{[k]}) - \exp(q^{[k]} - q^{[k-1]})$$ \hfill (3)

along with its variational symmetries,

$$q^{[k]}_2 = (q^{[k]}_1)^2 + \exp(q^{[k+1]} - q^{[k]}) + \exp(q^{[k]} - q^{[k-1]})$$

$$q^{[k]}_3 = (q^{[k]}_1)^3 + q^{[k+1]}_1 \exp(q^{[k+1]} - q^{[k]}) + q^{[k-1]}_1 \exp(q^{[k]} - q^{[k-1]}) + 2q^{[k]}_1 \left( \exp(q^{[k+1]} - q^{[k]}) + \exp(q^{[k]} - q^{[k-1]}) \right)$$ \hfill (4)

The hierarchy $[3]–[4]$ has a Lagrangian 1-form with coefficients

$$\mathcal{L}_1 = \sum_k \left( \frac{1}{2} (q^{[k]}_1)^2 - \exp(q^{[k]} - q^{[k-1]}) \right)$$

$$\mathcal{L}_2 = \sum_k \left( q^{[k]}_1 q^{[k]}_2 - \frac{1}{3} (q^{[k]}_1)^3 - (q^{[k]}_1 + q^{[k-1]}_1) \exp(q^{[k]} - q^{[k-1]}) \right)$$

$$\mathcal{L}_3 = \sum_k \left( -\frac{1}{4} (q^{[k]}_1)^4 - \left((q^{[k+1]}_1)^2 + q^{[k+1]}_1 q^{[k]}_1 + (q^{[k]}_1)^2\right) \exp(q^{[k+1]} - q^{[k]}) \right.$$

$$\left. + q^{[k]}_1 q^{[k]}_3 - \exp(q^{[k+2]} - q^{[k]}) - \frac{1}{2} \exp(2(q^{[k+1]} - q^{[k]})) \right)$$

We recover Equation (3), but for the other equations of the hierarchy we only get a differentiated form. However, we do get their evolutionary form, as in Equation (4), from the multi-time Euler-Lagrange equations

$$\delta_1 \mathcal{L}_1 = 0 \iff q^{[k]}_{1t} = e^{q^{[k+1]} - q^{[k]}} - e^{q^{[k]} - q^{[k-1]}}$$

$$\delta_2 \mathcal{L}_2 = 0 \iff q^{[k]}_{12} = (q^{[k]}_1 + q^{[k+1]}_1) e^{q^{[k+1]} - q^{[k]}} - (q^{[k]}_1 + q^{[k]}_1) e^{q^{[k]} - q^{[k-1]}}$$

$$\vdots$$

We recover Equation (3), but for the other equations of the hierarchy we only get a differentiated form. However, we do get their evolutionary form, as in Equation (4), from the multi-time Euler-Lagrange equations

$$\delta_2 \mathcal{L}_2 = 0, \quad \delta_3 \mathcal{L}_3 = 0, \quad \vdots$$

The multi-time Euler-Lagrange equations of type (2) are trivially satisfied in this case: $\frac{\delta \mathcal{L}_i}{\delta q^{[k]}_j} = q^{[k]}_j$ for all $j$. 

2.2 Lagrangian 2-forms

Theorem 2.4 ([28]). Consider the Lagrangian 2-form

\[ \mathcal{L}[u] = \sum_{i<j} \mathcal{L}_{ij}[u] \, dt_i \wedge dt_j, \]

depending on an arbitrary number of derivatives of \( u \). A field \( u \) is critical in the pluri-Lagrangian sense if and only if it satisfies the multi-time Euler-Lagrange equations

\[ \frac{\delta_{ij} \mathcal{L}_{ij}}{\delta u_I} = 0 \quad \forall I \not\ni t_i, \quad \text{(5)} \]
\[ \frac{\delta_{ij} \mathcal{L}_{ij}}{\delta u_{It_j}} - \frac{\delta_{ik} \mathcal{L}_{ik}}{\delta u_{It_k}} = 0 \quad \forall I \not\ni t_i, \quad \text{(6)} \]
\[ \frac{\delta_{ij} \mathcal{L}_{ij}}{\delta u_{It_jt_k}} + \frac{\delta_{ik} \mathcal{L}_{jk}}{\delta u_{It_jt_k}} + \frac{\delta_{ki} \mathcal{L}_{ki}}{\delta u_{It_kt_i}} = 0 \quad \forall I, \quad \text{(7)} \]

for all triples \((i, j, k)\) of distinct indices, where

\[ \frac{\delta_{ij}}{\delta u_I} = \sum_{\alpha, \beta=0}^{\infty} (-1)^{\alpha+\beta} \frac{\partial^\alpha}{\partial t^\alpha_i} \frac{\partial^\beta}{\partial t^\beta_j}. \]

Example 2.5. A Lagrangian 2-form for the potential KdV hierarchy was first given in [28]. It is instructive to look at just two of the equations embedded in \( \mathbb{R}^3 \). Then the Lagrangian 2-form has three coefficients,

\[ \mathcal{L} = \mathcal{L}_{12} \, dt_1 \wedge dt_2 + \mathcal{L}_{13} \, dt_1 \wedge dt_3 + \mathcal{L}_{23} \, dt_2 \wedge dt_3, \]

where \( t_1 \) is viewed as the space variable. We can take

\[ \mathcal{L}_{12} = -u_1^3 - \frac{1}{2} u_1 u_{111} + \frac{1}{2} u_1 u_2, \]
\[ \mathcal{L}_{13} = \frac{5}{2} u_1^4 + 5 u_1 u_1^2 - \frac{1}{2} u_1 u_{111} + \frac{1}{2} u_1 u_3, \]

where \( u_i \) is a shorthand notation for the partial derivative \( u_i \), and similar notations are used for higher derivatives. These are the classical Lagrangians of the potential KdV hierarchy. However, their classical Euler-Lagrange equations give the hierarchy only in a differentiated form,

\[ u_{12} = 6u_1 u_{11} + u_{1111}, \]
\[ u_{13} = 30u_1^2 u_{11} + 20u_1 u_{1111} + 10u_1 u_{11111} + u_{1111111}. \]

The Lagrangian 2-form also contains a coefficient

\[ \mathcal{L}_{23} = 3u_1^5 - \frac{15}{2} u_1^2 u_{11} + 10u_1^3 u_{111} - 5u_1^3 u_2 + \frac{7}{2} u_1^2 u_{111} + 3u_1 u_{111}^2 - 6u_1 u_{1111} \]
\[ + \frac{3}{2} u_{11111} + 10u_1 u_{111}u_{12} - \frac{5}{2} u_1^2 u_2 - 5u_1 u_{111} u_2 + \frac{3}{2} u_1^2 u_3 - \frac{1}{2} u_{111} \]
\[ + \frac{1}{2} u_{111} u_{1111} - u_{111} u_{112} + \frac{1}{2} u_1 u_{113} + u_{1111} u_{12} - \frac{1}{2} u_{11} u_{13} - \frac{1}{2} u_{11111} u_2 \]
\[ + \frac{1}{2} u_{111} u_3 \]
which does not have a classical interpretation, but contributes meaningfully in the pluri-
Lagrangian formalism. In particular, the multi-time Euler-Lagrange equations
\[
\frac{\delta_1 L_{12}}{\delta u_1} + \frac{\delta_3 L_{23}}{\delta u_3} = 0 \quad \text{and} \quad \frac{\delta_3 L_{13}}{\delta u_1} - \frac{\delta_2 L_{23}}{\delta u_3} = 0
\]
yield the potential KdV equations in their evolutionary form,
\[
\begin{align*}
    u_2 &= 3u_1^2 + u_{111}, \\
    u_3 &= 10u_1^3 + 5u_{11}^2 + 10u_1 u_{111} + u_{11111}.
\end{align*}
\]
All other multi-time Euler-Lagrange equations are consequences of these evolutionary
equations.

This example can be extended to contain an arbitrary number of equations from the
potential KdV hierarchy. The coefficients $L_{ij}$ will be Lagrangians of the individual
equations, whereas the $L_{ij}$ for $i, j > 1$ do not appear in the traditional Lagrangian picture.

**Example 2.6.** The Boussinesq equation
\[
u_{22} = 12u_{111} - 3u_{1111}
\]
is of second order in its time $t_2$, but the higher equations of its hierarchy are of first order
in their respective times, beginning with
\[
u_3 = -6u_{12} + 3u_{112}.
\]
A Lagrangian 2-form for this system has coefficients
\[
\begin{align*}
    L_{12} &= \frac{1}{2} u_2^2 - 2u_1^3 - \frac{3}{2} u_{11}^2, \\
    L_{13} &= 2u_2 u_3 + 6u_1^4 + 27u_1 u_{11}^2 - 6u_{12} u_2 + \frac{9}{2} u_{111}^2 - \frac{3}{2} u_{12}^2, \\
    L_{23} &= 24u_1^2 u_2 + 18u_{11} u_{12} + 9u_{11}^2 u_2 - 18u_1 u_{111} u_2 - 2u_2^3 - 6u_2 u_{22} \\
        &\quad + 6u_3^2 + 9u_{111} u_{112} + 3u_{111} u_{13} + 3u_{12} u_{22} - 3u_{111} u_3.
\end{align*}
\]
They can be found in [30] with a different scaling of $L$ and a different numbering of the
time variables. Equation (8) is equivalent to the Euler-Lagrange equation
\[
\frac{\delta_{12} L_{12}}{\delta u} = 0
\]
and Equation (9) to
\[
\frac{\delta_{13} L_{13}}{\delta u_2} = 0.
\]
All other multi-time Euler-Lagrange equations are differential consequences of Equations
(8) and (9). As in the previous example, it is possible to extend this 2-form to represent
an arbitrary number of equations from the hierarchy.

Further examples of pluri-Lagrangian 2-form systems can be found in [21, 22, 29, 30].
3 Hamiltonian structure of Lagrangian 1-form systems

A connection between Lagrangian 1-form systems and Hamiltonian or symplectic systems was found in [26], both in the continuous and the discrete case. Here we specialize that result to the common case where one coefficient of the Lagrangian 1-form is a mechanical Lagrangian and all others are linear in their respective time-derivatives. We formulate explicitly the underlying symplectic structures, which will provide guidance for the case of Lagrangian 2-form systems. Since some of the coefficients of the Lagrangian form will be linear in velocities, it is helpful to first have a look at the Hamiltonian formulation for Lagrangians of this type, independent of a pluri-Lagrangian structure.

3.1 Lagrangians that are linear in velocities

Let the configuration space be a finite-dimensional real vector space $Q = \mathbb{R}^N$ and consider a Lagrangian $\mathcal{L} : TQ \to \mathbb{R}$ of the form

$$\mathcal{L}(q, q_t) = p(q)^T q_t - V(q),$$

where

$$\det \left( \frac{\partial p}{\partial q} - \left( \frac{\partial p}{\partial q} \right)^T \right) \neq 0. \quad (11)$$

Note that $p$ denotes a function of the position $q$; later on we will use $\pi$ to denote the momentum as an element of cotangent space. If $Q$ is a manifold, the arguments of this subsection will still apply if there exists local coordinates in which the Lagrangian is of the form (10). The Euler-Lagrange equations are first order ODEs:

$$\dot{q} = -\left( \left( \frac{\partial p}{\partial q} \right)^T - \frac{\partial p}{\partial q} \right)^{-1} \nabla V,$$

where $\nabla V = \left( \frac{\partial V}{\partial q} \right)^T$ is the gradient of $V$.

Note that Equation (11) implies that $Q$ is even-dimensional, hence $Q$ admits a (local) symplectic structure. Instead of a symplectic form on $T^*Q$, the Lagrangian system preserves a symplectic form on $Q$ itself [2] [20]:

$$\omega = \sum_i dp_i(q) \wedge dq_i = \sum_{i,j} -\frac{\partial p_i}{\partial q_j} dq_j \wedge dq_i = \sum_{i<j} \left( \frac{\partial p_i}{\partial q_j} - \frac{\partial p_j}{\partial q_i} \right) dq_i \wedge dq_j,$$

which is non-degenerate by virtue of Equation (11).

**Proposition 3.1.** The Euler-Lagrange equation (12) of the Lagrangian (10) corresponds to a Hamiltonian vector field with respect to the symplectic structure $\omega$, with Hamilton function $V$. 

Proof. The Hamiltonian vector field $X = \sum_i X_i \frac{\partial}{\partial q_i}$ of the Hamilton function $V$ with respect to $\omega$ satisfies

$$i_X \omega = dV,$$

where

$$i_X \omega = \sum_i \sum_{j \neq i} \left( \frac{\partial p_j}{\partial q_i} - \frac{\partial p_i}{\partial q_j} \right) X_j dq_i$$

and

$$dV = \sum_i \frac{\partial V}{\partial q_i} dq_i.$$

Hence

$$X = \left( \left( \frac{\partial p}{\partial q} \right)^T - \frac{\partial p}{\partial q} \right)^{-1} \nabla V,$$

which is the vector field corresponding to the Euler-Lagrange equation (12). ■

3.2 From pluri-Lagrangian to Hamiltonian systems

On a finite-dimensional real vector space $Q$, consider a Lagrangian 1-form $L = \sum_i L_i dt_i$ consisting of a mechanical Lagrangian

$$L_1(q, q_1) = \frac{1}{2} |q_1|^2 - V_1(q),$$

where $|q_1|^2 = q_1^T q_1$, and additional coefficients of the form

$$L_i(q, q_1, q_i) = q_1^T q_i - V_i(q, q_1) \quad \text{for } i \geq 2,$$

where the indices of $q$ denote partial derivatives, $q_i = \frac{dq_i}{dt_i}$, whereas the indices of $L$ and $V$ are labels. We have chosen the Lagrangian coefficients such that they share a common momentum $p = q_1$, which is forced upon us by the multi-time Euler-Lagrange equation (2). Note that for each $i$, the coefficient $L_i$ contains derivatives of $q$ with respect to $t_1$ and $t_i$ only. Many Lagrangian 1-forms are of this form, including the Toda hierarchy, presented in Example 2.3.

The nontrivial multi-time Euler-Lagrange equations are

$$\frac{\delta_1 L_1}{\delta q} = 0 \iff q_{11} = -\frac{\partial V_1}{\partial q},$$

and

$$\frac{\delta_i L_i}{\delta q_1} = 0 \iff q_i = \frac{\partial V_i}{\partial q_1} \quad \text{for } i \geq 2,$$
with the additional condition that
\[ \frac{\delta_i L_i}{\delta q} = 0 \Leftrightarrow q_{ii} + \frac{\partial V_i}{\partial q} = 0. \]

Hence the multi-time Euler-Lagrange equations are overdetermined. Only for particular choices of \( V_i \) will the last equation be a differential consequence of the other multi-time Euler-Lagrange equations. The existence of suitable \( V_i \) for a given hierarchy could be taken as a definition of its integrability.

Note that there is no multi-time Euler-Lagrange equation involving the variational derivative
\[ \frac{\delta_1 L_i}{\delta q} = \frac{\partial V_i}{\partial q} - \frac{d}{dt_1} \frac{\partial V_i}{\partial q_1} \]
because of the mismatch between the time direction \( t_1 \) in which the variational derivative acts and the index \( i \) of the Lagrangian coefficient. The multi-time Euler-Lagrange equations of the type
\[ \frac{\delta_i L_i}{\delta q_i} = \frac{\delta_j L_j}{\delta q_j} \]
all reduce to the trivial equation \( q_1 = q_1 \), expressing the fact that all \( L_i \) yield the same momentum.

Since \( L_1 \) is regular, \( \det \left( \frac{\partial^2 L_1}{\partial q_i \partial q_j} \right) \neq 0 \), we can find a canonical Hamiltonian for the first equation by Legendre transformation,
\[ H_1(q, \pi) = \frac{1}{2} |\pi|^2 + V_1(q), \]
where we use \( \pi \) to denote the cotangent space coordinate and \( |\pi|^2 = \pi^T \pi \).

For \( i \geq 2 \) we consider \( r = q_1 \) as a second dependent variable. In other words, we double the dimension of the configuration space, which is now has coordinates \((q, r) = (q, q_1)\). The Lagrangians \( L_i(q, r, q_i, r_i) = rq_i - V_i(q, r) \) are linear in velocities. We have \( p(q, r) = r \), hence the symplectic form \([13]\) is
\[ \omega = dr \wedge dq. \]
This is the canonical symplectic form, with the momentum replaced by \( r = q_1 \). Hence we can consider \( r \) as momentum, thus identifying the extended configuration space spanned by \( q \) and \( r \) with the phase space \( T^*Q \).

Applying Proposition 3.1, we arrive at the following result:

**Theorem 3.2.** The multi-time Euler-Lagrange equations of a 1-form with coefficients \([14]-[15]\) are equivalent, under the identification \( \pi = q_1 \), to a system of Hamiltonian equations with respect to the canonical symplectic form \( \omega = d\pi \wedge dq \), with Hamilton functions
\[ H_1(q, \pi) = \frac{1}{2} |\pi|^2 + V_1(q) \quad \text{and} \quad H_i(q, \pi) = V_i(q, \pi) \quad \text{for} \ i \geq 2 \]
Example 3.3. From the Lagrangian 1-form for the Toda lattice given in Example 2.3 we find

\[ H_1 = \sum_k \left( \frac{1}{2} \left( \pi[k] \right)^2 + \exp(q[k] - q[k-1]) \right), \]

\[ H_2 = \sum_k \left( \frac{1}{3} \left( \pi[k] \right)^3 + \left( \pi[k] + \pi[k-1] \right) \exp(q[k] - q[k-1]) \right), \]

\[ H_3 = \sum_k \left( \frac{1}{4} \left( \pi[k] \right)^4 + \left( \pi[k+1] \right)^2 + \pi[k+1] \pi[k] + \left( \pi[k] \right)^2 \right) \exp(q[k+1] - q[k]) \]

\[ + \exp(q[k+2] - q[k]) + \frac{1}{2} \exp(2(q[k+1] - q[k])) \right), \]

\[ \vdots \]

We have limited the discussion in this section to the case where \( \mathcal{L}_1 \) is quadratic in the velocity. There are some interesting examples that do not fall into this category, like the Volterra lattice, which has a Lagrangian linear in velocities, and the relativistic Toda lattice, which has a Lagrangian with a more complicated dependence on velocities (see e.g. [25] and the references therein). The discussion above can be adapted to other types of Lagrangian 1-forms if one of its coefficients \( \mathcal{L}_i \) has an invertible Legendre transform, or if they are collectively Legendre-transformable as described in [26].

3.3 From Hamiltonian to Pluri-Lagrangian systems

The procedure from Section 3.2 can be reversed to construct a Lagrangian 1-form from a number of Hamiltonians.

Theorem 3.4. Consider Hamilton functions \( H_i : T^*Q \to \mathbb{R} \), with \( H_1(q, \pi) = \frac{1}{2} |\pi|^2 + V_1(q) \). Then the multi-time Euler-Lagrange equations of the Lagrangian 1-form \( \sum_i \mathcal{L}_i dt_i \) with

\[ \mathcal{L}_1 = \frac{1}{2} |q_1|^2 - V_1(q) \]

\[ \mathcal{L}_i = q_1 q_i - H_i(q, q_1) \quad \text{for } i \geq 2 \]

are equivalent to the Hamiltonian equations under the identification \( \pi = q_1 \).

Proof. Identifying \( \pi = q_1 \), the multi-time Euler-Lagrange equations of the type [1] are

\[ \frac{\delta_1 \mathcal{L}_1}{\delta q} = 0 \iff q_{11} = - \frac{\partial V_1(q)}{\partial q}, \]

\[ \frac{\delta_i \mathcal{L}_i}{\delta q_1} = 0 \iff q_i = \frac{\partial H_i(q, \pi)}{\partial p}, \]

\[ \frac{\delta_i \mathcal{L}_i}{\delta q} = 0 \iff \pi_i = - \frac{\partial H_i(q, \pi)}{\partial q}. \]

The multi-time Euler-Lagrange equations of the type [2] are trivially satisfied because

\[ \frac{\delta_i \mathcal{L}_i}{\delta q_i} = q_1 \]

for all \( i \). ■
Note that the statement of Theorem 3.4 does not require the Hamiltonian equations to commute, i.e. it is not imposed that the Hamiltonian vector fields $X_{H_i}$ associated to the Hamilton functions $H_i$ satisfy $[X_{H_i}, X_{H_j}] = 0$. However, if they do not commute then for a generic initial condition $(q_0, \pi_0)$ there will be no solution $(q, \pi) : \mathbb{R}^N \to T^*Q$ to the equations
\[
\frac{\partial}{\partial t_i}(q(t_1, \ldots, t_N), \pi(t_1, \ldots, t_N)) = X_{H_i}(q(t_1, \ldots, t_N), \pi(t_1, \ldots, t_N)) \quad (i = 1, \ldots, N),
\]
\[
(q(0, \ldots, 0), \pi(0, \ldots, 0)) = (q_0, \pi_0).
\]

Hence the relevance of Theorem 3.4 lies almost entirely in the case of commuting Hamiltonian equations. If they do not commute then it is an (almost) empty statement because neither the system of Hamiltonian equations nor the multi-time Euler-Lagrange equations will have solutions for generic initial data.

**Example 3.5.** The Kepler Problem, describing the motion of a point mass around a gravitational center, is one of the classic examples of a completely integrable system. It possesses Poisson-commuting Hamiltonians $H_1, H_2, H_3 : T^*\mathbb{R}^3 \to \mathbb{R}$ given by
\[
H_1(q, \pi) = \frac{1}{2}||\pi||^2 - ||q||^{-1}, \quad \text{the energy, Hamiltonian for the physical motion,}
\]
\[
H_2(q, \pi) = (q \times \pi) \cdot e_z, \quad \text{the 3rd component of the angular momentum, and}
\]
\[
H_3(q, \pi) = ||q \times \pi||^2, \quad \text{the squared magnitude of the angular momentum,}
\]
where $q = (x, y, z)$ and $e_z$ is the unit vector in the z-direction. The corresponding coefficients of the Lagrangian 1-form are
\[
L_1 = \frac{1}{2}||q_1||^2 + ||q||^{-1},
\]
\[
L_2 = q_1 \cdot q_2 - (q \times q_1) \cdot e_z,
\]
\[
L_3 = q_1 \cdot q_3 - ||q \times q_1||^2.
\]

The multi-time Euler-Lagrange equations are
\[
\frac{\delta L_1}{\delta q} = 0 \Rightarrow q_{11} = \frac{q}{||q||^3},
\]
the physical equations of motion,
\[
\frac{\delta L_2}{\delta q_1} = 0 \Rightarrow q_2 = e_z \times q,
\]
\[
\frac{\delta L_2}{\delta q} = 0 \Rightarrow q_{12} = -q_1 \times e_z,
\]
describing a rotation around the z-axis, and
\[
\frac{\delta L_3}{\delta q_1} = 0 \Rightarrow q_3 = 2(q \times q_1) \times q,
\]
\[
\frac{\delta L_3}{\delta q} = 0 \Rightarrow q_{13} = 2(q \times q_1) \times q_1,
\]
describing a rotation around the angular momentum vector.
3.4 Closedness and involutivity

In the pluri-Lagrangian theory, the exterior derivative $d\mathcal{L}$ is constant on solutions (see Proposition A.2 in the Appendix). In many cases this constant is zero, i.e. the Lagrangian 1-form is closed on solutions. Here we relate this property to the vanishing of Poisson brackets between the Hamilton functions.

**Proposition 3.6** ([26, Theorem 3]). Consider a Lagrangian 1-form $\mathcal{L}$ as in Section 3.2 and the corresponding Hamilton functions $H_i$. On solutions to the multi-time Euler-Lagrange equations, and identifying $\pi = p(q, q_1) = \frac{\partial \mathcal{L}_i}{\partial q_i}$, there holds

$$
\frac{d\mathcal{L}_j}{dt} - \frac{d\mathcal{L}_i}{dt} = p_j q_i - p_i q_j
$$

where $\{\cdot, \cdot\}$ denotes the canonical Poisson bracket and $p_j$ and $q_j$ are shorthand for $\frac{dp}{dt_j}$ and $\frac{dq}{dt_j}$.

**Proof.** On solutions of the multi-time Euler-Lagrange equations there holds

$$
\frac{d\mathcal{L}_j}{dt} = \frac{\partial \mathcal{L}_j}{\partial q} q_i + \frac{\partial \mathcal{L}_j}{\partial q_1} q_{1i} + \frac{\partial \mathcal{L}_j}{\partial q_j} q_{ij}
$$

$$
= \left( \frac{d}{dt_j} \frac{\partial \mathcal{L}_j}{\partial q} \right) q_i + \frac{\partial \mathcal{L}_j}{\partial q_j} q_{ij}
$$

$$
= p_j q_i + pq_{ij}.
$$

Hence

$$
\frac{d\mathcal{L}_j}{dt} - \frac{d\mathcal{L}_i}{dt} = p_j q_i - p_i q_j.
$$

(17)

Alternatively, we can calculate this expression using the Hamiltonian formalism. We have

$$
\frac{d\mathcal{L}_j}{dt} - \frac{d\mathcal{L}_i}{dt} = \frac{d}{dt_j} (pq_j - H_j) - \frac{d}{dt_j} (pq_i - H_i)
$$

$$
= p_i q_j - p_j q_i + 2\{H_j, H_i\}.
$$

Combined with Equation (17), this implies Equation (16).

As a corollary we have:

**Theorem 3.7.** The Hamiltonians $H_i$ from Theorem 3.2 are in involution if and only if $d\mathcal{L} = 0$ on solutions.

All examples of Lagrangian 1-forms discussed so far satisfy $d\mathcal{L} = 0$ on solutions. This need not be the case.
Example 3.8. Let us consider a system of commuting equations that is not Liouville integrable. Fix a constant $c \neq 0$ and consider the 1-form $\mathcal{L} = \mathcal{L}_1 \, dt_1 + \mathcal{L}_2 \, dt_2$ with

$$\mathcal{L}_1[r, \theta] = \frac{1}{2} r^2 \theta_1^2 + \frac{1}{2} r_1^2 - V(r) - c\theta,$$

which for $c = 0$ would describe a central force in the plane governed by the potential $V$, and

$$\mathcal{L}_2[r, \theta] = r^2 \theta_1 (\theta_2 - 1) + r_1 r_2.$$

Its multi-time Euler-Lagrange equations are

$$r_{11} = -V'(r) + r \theta_1^2,$$

$$\frac{d}{dt_1} (r^2 \theta_1) = -c,$$

$$r_2 = 0,$$

$$\theta_2 = 1,$$

and consequences thereof. Notably, we have

$$\frac{d\mathcal{L}_2}{dt_1} - \frac{d\mathcal{L}_1}{dt_2} = c$$

on solutions, hence $d\mathcal{L}$ is nonzero.

By Theorem 3.2 the multi-time Euler-Lagrange equations are equivalent to the canonical Hamiltonian systems with

$$H_1(r, \theta, \pi, \sigma) = \frac{1}{2} \sigma^2 + \frac{1}{2} \pi^2 + V(r) + c\theta,$$

$$H_2(r, \theta, \pi, \sigma) = \sigma,$$

where $\pi$ and $\sigma$ are the conjugate momenta to $r$ and $\theta$. The Hamiltonians are not in involution, but rather

$$\{H_2, H_1\} = c = \frac{d\mathcal{L}_2}{dt_1} - \frac{d\mathcal{L}_1}{dt_2}.$$

4 Hamiltonian structure of Lagrangian 2-form systems

In order to generalize the results from Section 3 to the case of 2-forms, we need to carefully examine the relevant geometric structure. A useful tool for this is the variational bicomplex, which is also used in Appendix A to study the multi-time Euler-Lagrange equations.

4.1 The variational bicomplex

To facilitate the variational calculus in the pluri-Lagrangian setting, it is useful to consider the variation operator $\delta$ as an exterior derivative, acting in the fiber $J^\infty$ of the infinite jet
bundle. We call $\delta$ the \textit{vertical exterior derivative} and $d$, which acts in the base manifold $M$, the \textit{horizontal exterior derivative}. Together they provide a double grading of the space $\Omega(M \times J^\infty)$ of differential forms on the jet bundle. The space of $(a, b)$-\textit{forms} is generated by those $(a + b)$-forms structured as

$$f[u] \delta u_{i_1} \wedge \ldots \wedge \delta u_{i_a} \wedge dt_{j_1} \ldots \wedge dt_{j_b}.$$ 

We denote the space of $(a, b)$-forms by $\Omega(a, b) \subset \Omega^{a+b}(M \times J^\infty)$. We call elements of $\Omega(0, b)$ horizontal forms and elements of $\Omega(a, 0)$ vertical forms. The Lagrangian is a horizontal $d$-form, $L \in \Omega^{0,d}$.

The horizontal and vertical exterior derivatives are characterized by the anti-derivation property,

$$d (\omega^{p_1,q_1} \wedge \omega^{p_2,q_2}) = d\omega^{p_1,q_1} \wedge \omega^{p_2,q_2} + (-1)^{p_1+q_1} \omega^{p_1,q_1} \wedge d\omega^{p_2,q_2},$$

$$\delta (\omega^{p_1,q_1} \wedge \omega^{p_2,q_2}) = \delta\omega^{p_1,q_1} \wedge \omega^{p_2,q_2} + (-1)^{p_1+q_1} \omega^{p_1,q_1} \wedge \delta\omega^{p_2,q_2},$$

where the upper indices denote the type of the forms, and by the way they act on $(0, 0)$-forms, and basic $(1, 0)$ and $(0, 1)$-forms:

$$df[u] = \sum_j \partial_j f[u] \ dt_j, \quad \delta f[u] = \sum_i \frac{\partial f[u]}{\partial u_i} \delta u_i,$$

$$d(\delta u_I) = - \sum_j \delta u_{Ij} \wedge dt_j, \quad \delta(\delta u_I) = 0,$$

$$d(dt_j) = 0, \quad \delta(dt_j) = 0.$$ 

One can verify that $d + \delta : \Omega^{a+b} \to \Omega^{a+b+1}$ is the usual exterior derivative and that

$$\delta^2 = d^2 = \delta d + d\delta = 0.$$ 

Time-derivatives $\partial_j$ act on vertical forms as $\partial_j(\delta u_I) = \delta u_{Ij}$, on horizontal forms as $\partial_j(dt_k) = 0$, and obey the Leibniz rule with respect to the wedge product. As a simple but important example, note that

$$d(f[u] \delta u_I) = \sum_{j=1}^N \partial_j f[u] \ dt_j \wedge \delta u_I - f[u] \delta u_{Ij} \wedge dt_j = \sum_{j=1}^N -\partial_j(f[u]) \delta u_I \wedge dt_j.$$ 

The spaces $\Omega(a, b)$, for $a \geq 0$ and $0 \leq b \leq N$, related to each other by the maps $d$ and $\delta$, are collectively known as the \textit{variational bicomplex} [8, Chapter 19]. A slightly different version of the variational bicomplex, using contact 1-forms instead of vertical forms, is presented in [1]. We will not discuss the rich algebraic structure of the variational bicomplex here.

For a horizontal $(0, d)$-form $L[u]$, the variational principle

$$\delta \int_\Gamma L[u] = \delta \int_\Gamma \sum_{i_1 < \ldots < i_d} L_{i_1,\ldots,i_d}[u] \ dt_{i_1} \wedge \ldots \wedge dt_{i_d} = 0$$
can be understood as follows. Every vertical vector field \( V = v(t_1, \ldots, t_a) \frac{\partial}{\partial u} \), such that its prolongation
\[
\text{pr} V = \sum_I v_I \frac{\partial}{\partial u_I}
\]
vanishes on the boundary \( \partial \Gamma \), must satisfy
\[
\int_\Gamma \iota_{\text{pr} V} \delta \mathcal{L} = \int_\Gamma \sum_{i_1 < \ldots < i_d} \iota_{\text{pr} V} (\delta \mathcal{L}_{i_1, \ldots, i_d}[u]) \, dt_{i_1} \wedge \ldots \wedge dt_{i_d} = 0.
\]
Note that the integrand is a horizontal form, so the integration takes place on \( \Gamma \subset M \), independent of the bundle structure.

### 4.2 The space of functionals and its pre-symplectic structure

In the rest of our discussion, we will single out the variable \( t_1 = x \) and view it as the space variable, as opposed to the time variables \( t_2, \ldots, t_N \). For ease of presentation we will limit the discussion here to real scalar fields, but it is easily extended to complex or vector-valued fields. We consider functions \( u : \mathbb{R} \to \mathbb{R} : x \mapsto u(x) \) as fields at a fixed time. Let \( J^\infty \) be the fiber of the corresponding infinite jet bundle, where the prolongation of \( u \) has coordinates \([u] = (u, u_x, u_{xx}, \ldots)\). Consider the space of functions of the infinite jet of \( u \),
\[
\mathcal{V} = \{ v : J^\infty \to \mathbb{R} \}.
\]
Note that the domain \( J^\infty \) is the fiber of the jet bundle, hence the elements \( v \in \mathcal{V} \) depend on \( x \) only through \( u \). We will be dealing with integrals \( \int v \, dx \) of elements \( v \in \mathcal{V} \). In order to avoid convergence questions, we understand the symbol \( \int v \, dx \) as a formal integral, defined as the equivalence class of \( v \) modulo space-derivatives. In other words, we consider the space of functionals
\[
\mathcal{F} = \mathcal{V} / \partial_x \mathcal{V},
\]
where
\[
\partial_x = \frac{d}{dx} = \sum_I u_{Ix} \frac{\partial}{\partial u_I}.
\]

The variation of an element of \( \mathcal{F} \) is computed as
\[
\delta \int v \, dx = \int \frac{\delta v}{\delta u} \delta u \wedge dx,
\]
where
\[
\frac{\delta}{\delta u} = \sum_{\alpha=0}^\infty (-1)^\alpha \partial_x^\alpha \frac{\partial}{\partial u_{x^\alpha}}.
\]
Equation (18) is independent of the choice of representative \( v \in \mathcal{V} \) because the variational derivative of a full \( x \)-derivative is zero.
Since $\mathcal{V}$ is a linear space, its tangent spaces can be identified with $\mathcal{V}$ itself. In turn, every $v \in \mathcal{V}$ can be identified with a vector field $v \frac{\partial}{\partial u}$. We will define Hamiltonian vector fields in terms of $\mathcal{F}$-valued forms on $\mathcal{V}$. An $\mathcal{F}$-valued 1-form $\theta$ can be represented as the integral of a $(1,1)$-form in the variational bicomplex,

$$\theta = \int \sum_k a_k[u] \delta u_x^k \wedge dx$$

and defines a map

$$\mathcal{V} \to \mathcal{F} : v \mapsto \iota_v \theta = \int \sum_k a_k[u] \partial^k_x v[u] dx.$$ 

This amounts to pairing the 1-form with the infinite jet prolongation of the vector field $v \frac{\partial}{\partial u}$. Note that $\mathcal{F}$-valued forms are defined modulo $x$-derivatives: $\int \partial_x \theta \wedge dx = 0$ because its pairing with any vector field in $\mathcal{V}$ will yield a full $x$-derivative, which represents the zero functional in $\mathcal{F}$. Hence the space of $\mathcal{F}$-valued 1-forms is $\Omega^{(1,1)}/\partial_x \Omega^{(1,1)}$.

An $\mathcal{F}$-valued 2-form

$$\omega = \int \sum_{k,\ell} a_{k,\ell}[u] \delta u_x^k \wedge \delta u_x^\ell \wedge dx$$

defines a skew-symmetric map

$$\mathcal{V} \times \mathcal{V} \to \mathcal{F} : (v, w) \mapsto \iota_v \iota_w \omega = \int \sum_{k,\ell} a_{k,\ell}[u] \left( \partial^k_x v[u] \partial^\ell_x w[u] - \partial^k_x w[u] \partial^\ell_x v[u] \right) dx$$

as well as a map from vector fields to $\mathcal{F}$-valued 1-forms

$$\mathcal{V} \to \Omega^{(1,1)}/\partial_x \Omega^{(1,1)} : v \mapsto \iota_v \omega = \int \sum_{k,\ell} a_{k,\ell}[u] \left( \partial^k_x v[u] \delta u_x^\ell - \partial^\ell_x v[u] \delta u_x^k \right) \wedge dx.$$ 

**Definition 4.1.** A closed $(2,1)$-form $\omega$ on $\mathcal{V}$ is called pre-symplectic.

Equivalently we can require the form to be vertically closed, i.e. closed with respect to $\delta$. Since the horizontal space is 1-dimensional ($x$ is the only independent variable) every $(a,1)$-form is closed with respect to the horizontal exterior derivative $d$, so only vertical closedness is a nontrivial property.

We choose to work with pre-symplectic forms instead of symplectic forms, because the non-degeneracy required of a symplectic form is a subtle issue in the present context. Consider for example the pre-symplectic form $\omega = \int \delta u \wedge \delta u_x \wedge dx$. It is degenerate because

$$\int \iota_v \omega = \int (v \delta u_x - v_x \delta u) \wedge dx = \int -2v_x \delta u \wedge dx,$$

which is zero whenever $v[u]$ is constant. However, if we restrict our attention to compactly supported fields, then a constant must be zero, so the restriction of $\omega$ to the space of compactly supported fields is non-degenerate.
Definition 4.2. A Hamiltonian vector field with Hamilton functional $\int H \, dx$ is an element $v \in V$ satisfying the relation
$$\int \iota_v \omega = \int \delta H \wedge dx.$$ 
Note that if $\omega$ is degenerate, we cannot guarantee existence or uniqueness of a Hamiltonian vector field in general.

4.3 From pluri-Lagrangian to Hamiltonian systems

We will consider two different types of Lagrangian 2-forms. The first type are those where for every $j$ the coefficient $L_{1j}$ is linear in $u_t^j$. This is the case for the 2-form for the potential KdV hierarchy from Example 2.5 and for the Lagrangian 2-forms of many other hierarchies like the AKNS hierarchy [21] and the modified KdV, Schwarzian KdV and Krichever-Novikov hierarchies [30]. The second type satisfy the same property for $j > 2$, but have a coefficient $L_{12}$ that is quadratic in $u_t^2$, as is the case for the Boussinesq hierarchy from Example 2.6.

4.3.1 When all $L_{1j}$ are linear in $u_t^j$

Consider a Lagrangian 2-form $L[u] = \sum_{i<j} L_{ij}[u] \, dt_i \wedge dt_j$, where for all $j$ the variational derivative $\frac{\delta_1 L_{1j}}{\delta u_t^j}$ does not depend on any $t_j$-derivatives, hence we can write
$$\frac{\delta_1 L_{1j}}{\delta u_t^j} = p[u]$$
for some function $p[u]$ depending on on an arbitrary number of space derivatives, but not on any time-derivatives. We use single square brackets $[\cdot]$ to indicate dependence on space derivatives only. Note that $p$ does not depend on the index $j$. This is imposed on us by the multi-time Euler-Lagrange equation stating that $\frac{\delta_1 L_{1j}}{\delta u_t^j}$ is independent of $j$.

Starting from these assumptions and possibly adding a full $x$-derivative (recall that $x = t_1$) we find that the coefficients $L_{1j}$ are of the form
$$L_{1j}[u] = p[u] u_j - h_j[u], \quad \text{(19)}$$
where $u_j$ is shorthand notation for the derivative $u_t^j$. Coefficients of this form appear in many prominent examples, like the potential KdV hierarchy and several hierarchies related to it [28, 29, 30] as well as the AKNS hierarchy [21]. Their Euler-Lagrange equations are
$$\mathcal{E}_p u_j - \frac{\delta_1 h_j[u]}{\delta u} = 0, \quad \text{(20)}$$
where $\mathcal{E}_p$ is the differential operator
$$\mathcal{E}_p = \sum_{k=0}^{\infty} \left( (-1)^k \frac{\partial^k}{\partial u_{xk}} \frac{\partial p}{\partial u_{xk}} - \frac{\partial p}{\partial u_{xk}} \frac{\partial^k}{\partial x} \right).$$
We can also write $\mathcal{E}_p = D_p^* - D_p$, where $D_p$ is the Fréchet derivative of $p$ and $D_p^*$ its adjoint [17, Eqs (5.32) resp. (5.79)].
Consider the pre-symplectic form
\[
\omega = -\delta p[u] \wedge \delta u \wedge dx
= -\sum_{k=1}^{\infty} \frac{\partial p}{\partial u_{x^k}} \delta u_{x^k} \wedge \delta u \wedge dx.
\] (21)

Inserting the vector field \( X = \chi \frac{\partial}{\partial u} \) we find
\[
\int \iota_X \omega = \int \sum_{k=0}^{\infty} \left( \frac{\partial p}{\partial u_{x^k}} \chi \delta u_{x^k} \wedge dx - \frac{\partial p}{\partial u_{x^k}} \chi \delta u \wedge dx \right)
= \int \sum_{k=0}^{\infty} \left( (-1)^k \partial^k_x \left( \frac{\partial p}{\partial u_{x^k}} \chi \right) - \frac{\partial p}{\partial u_{x^k}} \chi \delta u \wedge dx \right)
= \int \mathcal{E}_p \chi \delta u \wedge dx.
\]

From the Hamiltonian equation of motion
\[
\int \iota_X \omega = \int \delta h_j [u] \wedge dx
\]
we now obtain that the Hamiltonian vector field \( X = \chi \frac{\partial}{\partial u} \) associated to \( h_j \) satisfies
\[
\mathcal{E}_p \chi = \frac{\delta_1 h_j}{\delta u},
\]
which corresponds the Euler-Lagrange equation \(^2\) by identifying \( \chi = u_{t_j} \). This observation was made previously in the context of loop spaces in \(^16\) Section 1.3.

The Poisson bracket associated to the symplectic operator \( \mathcal{E}_p \) is formally given by
\[
\{ \int f \, dx, \int g \, dx \} = -\int \frac{\delta f}{\delta u} \mathcal{E}_p^{-1} \frac{\delta g}{\delta u} \, dx.
\] (22)

If the pre-symplectic form is degenerate, then \( \mathcal{E}_p \) will not be invertible. In this case \( \mathcal{E}_p^{-1} \) can be considered as a pseudo-differential operator and the Poisson bracket is called non-local \(^16\) Note that \( \{ \cdot, \cdot \} \) does not satisfy the Leibniz rule because there is no multiplication on the space \( \mathcal{F} \) of formal integrals. However, we can recover the Leibniz rule in one entry by introducing
\[
[f, g] = -\sum_{k=0}^{\infty} \frac{\partial f}{\partial u_{x^k}} \partial^k_x \mathcal{E}_p^{-1} \frac{\delta g}{\delta u}.
\]
Then we have
\[
\{ \int f \, dx, \int g \, dx \} = \int [f, g] \, dx
\]
and
\[
[fg, h] = f [g, h] + [f, h] g.
\]

In summary, we have the following result:
Theorem 4.3. Assume that $\frac{\delta h_j[u]}{\delta u}$ is in the image of $\mathcal{E}_p$ and has a unique inverse (possibly in some equivalence class) for each $j$. Then the evolutionary PDEs

$$u_j = \mathcal{E}_p^{-1}\frac{\delta h_j[u]}{\delta u},$$

which imply the Euler-Lagrange equations (20) of the Lagrangians (19), are Hamiltonian with respect to the symplectic form (21) and the Poisson bracket (22), with Hamilton functions $h_j$.

This theorem applies without assuming any kind of consistency of the system of multi-time Euler-Lagrange equations. Of course we are mostly interested in the case where the multi-time Euler-Lagrange equations are equivalent to an integrable hierarchy. In almost all known examples (see e.g. [28, 21, 30]) the multi-time Euler-Lagrange equations consist of an integrable hierarchy in its evolutionary form and differential consequences thereof. Hence the general picture suggested by these examples is that the multi-time Euler-Lagrange equations are equivalent to the equations $u_j = \mathcal{E}_p^{-1}\frac{\delta h_j[u]}{\delta u}$ form Theorem 4.3. In light of these observations, we emphasize the following consequence of Theorem 4.3.

Corollary 4.4. If the multi-time Euler-Lagrange equations are evolutionary, then they are Hamiltonian.

Example 4.5. The pluri-Lagrangian structure for the potential KdV hierarchy, given in Example 2.5 has $p = \frac{1}{2}u_x$. Hence

$$\mathcal{E}_p = -\partial_x \frac{\partial p}{\partial u_x} - \frac{\partial p}{\partial u_x} \partial_x = -\partial_x$$

and

$$\{ \int f \, dx, \int g \, dx \} = \int \frac{\delta f}{\delta u} \partial_x^{-1} \frac{\delta g}{\delta u} \, dx.$$ 

Here we assume that $\frac{\delta g}{\delta u}$ is in the image of $\partial_x$. Then $\partial_x^{-1} \frac{\delta g}{\delta u}$ is uniquely defined by the convention that it does not contain a constant term. If $f$ and $g$ depend only on derivatives of $u$, not on $u$ itself, this becomes the Gardner bracket [10]

$$\{ \int f \, dx, \int g \, dx \} = \int \left( \partial_x \frac{\delta f}{\delta u_x} \right) \frac{\delta g}{\delta u_x} \, dx.$$ 

The Hamilton functions are

$$h_2[u] = \frac{1}{2}u_xu_{xx} - \mathcal{L}_{12} = u_x^3 + \frac{1}{2}u_xu_{xxx},$$

$$h_3[u] = \frac{1}{2}u_xu_{xxx} - \mathcal{L}_{13} = 5u_x^4 - 5u_xu_{xx}^2 + \frac{1}{2}u_{xxx}^2,$$

$$\vdots$$

A related derivation of the Gardner bracket from the multi-symplectic perspective was given in [11]. It can also be obtained from the Lagrangian structure by Dirac reduction [15].
Example 4.6. The Schwarzian KdV hierarchy,
\[ u_2 = -\frac{3u_{11}^2}{2u_1} + u_{111}, \]
\[ u_3 = -\frac{45u_{1111}^4}{8u_1^3} + \frac{25u_{11}^2 u_{1111}}{2u_1^2} - \frac{5u_{1111}^2}{2u_1} - \frac{5u_{111} u_{11111}}{u_1} + u_{11111}, \]
\[ \vdots \]
has a pluri-Lagrangian structure with coefficients \[29\]
\[ L_{12} = \frac{u_3^2}{2u_1} - \frac{u_{11}^2}{2u_1^2}, \]
\[ L_{13} = \frac{u_5}{2u_1} - \frac{3u_{11}^4}{8u_1^4} + \frac{u_{1111}^2}{2u_1^2}, \]
\[ L_{23} = -\frac{45u_{1111}^6}{32u_1^6} + \frac{57u_{111111} u_{1111}}{16u_1^6} - \frac{19u_{111}^2 u_{11111}}{8u_1^4} + \frac{7u_{1111}^3 u_{111111}}{4u_1^4} - \frac{3u_{1111} u_{1111111}}{4u_1^4} - \frac{3u_{111} u_{1111} u_{111111}}{2u_1^4} \]
\[ + \frac{u_{11111} u_{11113}}{u_1^4} + \frac{u_{11111} u_{11115}}{u_1^4} - \frac{27u_{1111}^2 u_{11113}}{16u_1^4} + \frac{17u_{1111}^2 u_{11115}}{4u_1^4} - \frac{7u_{11111}^2 u_{11113}}{4u_1^4} - \frac{3u_{111} u_{1111} u_{111111}}{2u_1^4} \]
\[ + \frac{u_{111111} u_{11113}}{2u_1^2} + \frac{u_{111115}}{4u_1^2} - \frac{u_{11111} u_{11115}}{2u_1^2}, \]
\[ \vdots \]

In this example we have \( p = \frac{1}{2u_x} \), hence
\[ \mathcal{E}_p = -\partial_x \frac{\partial p}{\partial u_x} - \frac{\partial p}{\partial u_x} \partial_x = \frac{1}{u_x^2} \partial_x = \frac{1}{u_x} \partial_x = \frac{1}{u_x} \]
and
\[ \mathcal{E}_p^{-1} = u_x \partial_x^{-1} u_x. \]

This nonlocal operator seems to be the simplest Hamiltonian operator for the SKdV equation, see for example \[9, 31\]. The Hamilton functions for the first two equations of the hierarchy are
\[ h_2 = \frac{u_{11}^2}{2u_1^2} \quad \text{and} \quad h_3 = \frac{3u_{111}^4}{8u_1^4} - \frac{u_{11111}^2}{2u_1^2}. \]

4.3.2 When \( L_{12} \) is quadratic in \( u_{12} \)

Consider a Lagrangian 2-form \( \mathcal{L}[u] = \sum_{i<j} L_{ij}[u] \, dt_i \wedge dt_j \) with
\[ \mathcal{L}_{12} = \frac{1}{2} \alpha[u] u_{12}^2 - V[u], \quad (23) \]
and, for all \( j \geq 3 \), \( \mathcal{L}_{1j} \) of the form
\[
\mathcal{L}_{1j}[u] = \alpha[u]u_2u_j - h_j[u, u_2],
\]
where \([u, u_2] = (u, u_2, u_1, u_{12}, u_{111}, u_{1112}, \ldots)\) since the single bracket \([\ ]\) denotes dependence on the fields and their \( x \)-derivatives only (recall that \( x = t_1 \)). To write down the full set of multi-time Euler-Lagrange equations we need to specify all \( \mathcal{L}_{ij} \), but for the present discussion it is sufficient to consider the equations
\[
\frac{\delta L_{12}}{\delta u} = 0 \iff \alpha[u]u_{22} = -\frac{d\alpha[u]}{du_2}u_2 + \frac{1}{2}\sum_{k=0}^{\infty} (-1)^k \partial^k_x \left( \frac{\partial \alpha[u]}{\partial u_{x^k}} u_2^2 \right) - \frac{\delta_1 V[u]}{\delta u}
\]
and
\[
\frac{\delta_1 \mathcal{L}_{1j}}{\delta u_2} = 0 \iff \alpha[u]u_j = \frac{\delta_1 h_j[u, u_2]}{\delta u_2}.
\]
We assume that all other multi-time Euler-Lagrange equations are consequences of these.

Since \( \mathcal{L}_{12} \) is non-degenerate, the Legendre transform is invertible and allows us to identify \( \pi = \alpha[u]u_2 \). Consider the canonical symplectic form on formal integrals, where now the momentum \( \pi \) enters as a second field,
\[
\omega = \delta \pi \wedge \delta u \wedge dx.
\]
This defines the Poisson bracket
\[
\{ f dx, g dx \} = -\int \left( \frac{\delta f}{\delta \pi} \frac{\delta g}{\delta u} - \frac{\delta f}{\delta u} \frac{\delta g}{\delta \pi} \right) dx.
\]
The coefficients \( \mathcal{L}_{1j}[u] = \alpha[u]u_2u_j - h_j[u, u_2] \) are linear in their velocities \( u_j \), hence they are Hamiltonian with respect to the pre-symplectic form
\[
\delta (\alpha[u]u_2) \wedge \delta u \wedge dx,
\]
which equals \( \omega \) if we identify \( \pi = \alpha[u]u_2 \). Hence we find the following result.

**Theorem 4.7.** A hierarchy described by a Lagrangian 2-form with coefficients of the form \( (23) - (24) \) is Hamiltonian with respect to the canonical Poisson bracket \( (25) \), with Hamilton functions
\[
H_2[u, \pi] = \frac{1}{2} \frac{\pi^2}{\alpha[u]} + V[u]
\]
and
\[
H_j[u, \pi] = h_j \left[ u, \frac{\pi}{\alpha[u]} \right]
\]
for \( j \geq 3 \).
Example 4.8. The Lagrangian 2-form for the Boussinesq hierarchy from Example 2.6 leads to

\[ H_2 = \frac{1}{2} \pi^2 + 2u_1^3 + \frac{3}{2} u_1^2, \]

\[ H_3 = -6u_1^4 - 27u_1u_2^2 + 6u_1\pi - \frac{9}{2} u_{111}^2 - \frac{3}{2} \pi_1^2, \]

where the Legendre transform identifies \( \pi = u_2 \). Indeed we have

\[ \{ \int H_2 \, dx, \int u \, dx \} = \int \pi \, dx = \int u_2 \, dx, \]

\[ \{ \int H_2 \, dx, \int \pi \, dx \} = \int (12u_1 u_{11} - 3u_{111}) \, dx = \int \pi_2 \, dx, \]

and

\[ \{ \int H_3 \, dx, \int u \, dx \} = \int (-6u_1 \pi + 3\pi_{11}) \, dx = \int u_3 \, dx, \]

\[ \{ \int H_3 \, dx, \int \pi \, dx \} = \int (-72u_1^2 u_{11} + 108u_{11} u_{111} + 54u_1 u_{111} - 6\pi_1 - 9u_{111111}) \, dx \]

\[ = \int \pi_3 \, dx. \]

4.4 Closedness and involutivity

Let us now have a look at the relation between the closedness of the Lagrangian 2-form and the involutivity of the corresponding Hamiltonians.

Proposition 4.9. On solutions of the multi-time Euler-Lagrange equations of a Lagrangian 2-form with coefficients \( L_{ij} \) given by Equation (19), there holds

\[ \{ h_i, h_j \} = \int (p_i u_j - p_j u_i) \, dx = \int \left( \frac{dL_{ii}}{dt_j} - \frac{dL_{ij}}{dt_i} \right) \, dx, \]

where the Poisson bracket is given by Equation (22).

Proof. On solutions of the Euler-Lagrange equations we have

\[ \int \frac{dL_{ii}}{dt_j} \, dx = \int \left( \frac{\delta L_{ii}}{\delta u} u_j + \frac{\partial L_{ii}}{\partial u_i} u_{ij} \right) \, dx \]

\[ = \int \left( \left( \frac{d}{dt_i} \frac{\delta L_{ii}}{\delta u} \right) u_j + \frac{\partial L_{ii}}{\partial u_i} u_{ij} \right) \, dx \]

\[ = \int (p_i u_j + p_{ij}) \, dx. \]

It follows that

\[ \int \left( \frac{dL_{ii}}{dt_j} - \frac{dL_{ij}}{dt_i} \right) \, dx = \int (p_i u_j - p_j u_i) \, dx. \]

(26)

On the other hand we have that

\[ \int \left( \frac{dL_{ii}}{dt_j} - \frac{dL_{ij}}{dt_i} \right) \, dx = \int \left( \frac{d}{dt_j} (pu_i - h_i) - \frac{d}{dt_i} (pu_j - h_j) \right) \, dx \]

\[ = - \int (p_i u_j - p_j u_i) \, dx + 2\{ h_i, h_j \}. \]

Combined with Equation (27), this implies both identities in Equation (26).
Proposition 4.10. On solutions of the multi-time Euler-Lagrange equations of a Lagrangian 2-form with coefficients $L_{ij}$ given by Equations (23)–(24), there holds

$$\{H_i, H_j\} = \int (\pi_i u_j - \pi_j u_i) \, dx = \int \left( \frac{dL_{ij}}{dt_j} - \frac{dL_{ij}}{dt_i} \right) \, dx,$$

where the Poisson bracket is given by Equation (25) and the Hamilton functions $H_j$ are given in Theorem 4.7.

Proof. Analogous to the proof of Proposition 4.9, with $p[u]$ replaced by the field $\pi$. ■

Theorem 4.11. Let $L$ be a Lagrangian 2-form with coefficients $L_{ij}$ given by Equation (19) or by Equations (23)–(24). Consider the corresponding Hamiltonian structures, given by $H_{1i}$ or $H_{1j}$, as in Theorems 4.3 and 4.7 respectively. There holds $\{H_{1i}, H_{1j}\} = 0$ if and only if

$$\int \left( \frac{dL_{ij}}{dt_1} - \frac{dL_{1j}}{dt_i} + \frac{dL_{1i}}{dt_j} \right) \, dx = 0$$

on solutions of the multi-time Euler-Lagrange equations.

Proof. Recall that $t_1 = x$, hence $\frac{d}{dt_1} = \partial_x$. By definition of the formal integral as an equivalence class, we have $\int \partial_x L_{ij} \, dx = 0$. Hence the claim follows from Proposition 4.9 or Proposition 4.10. ■

It is known that $dL[u]$ is constant in the set of solutions $u$ to the multi-time Euler-Lagrange equations (see Proposition A.2). In most examples, one can verify using a trivial solution that this constant is zero.

Corollary 4.12. If a Lagrangian 2-form, with coefficients $L_{ij}[u]$ given by Equation (19) or by Equations (23)–(24), is closed for a solution $u$ to the pluri-Lagrangian problem, then $\{H_{1i}, H_{1j}\} = 0$ for all $i, j$.

All examples of Lagrangian 2-forms discussed so far satisfy $dL = 0$ on solutions. We now present a system where this is not the case.

Example 4.13. Consider a perturbation of the Boussinesq Lagrangian, obtained by adding $cu$ for some constant $c \in \mathbb{R}$,

$$L_{12} = \frac{1}{2} u_2^2 - 2u_1^3 - \frac{3}{2} u_{111}^2 + cu,$$

combined with the Lagrangian coefficients $L_{13} = u_2(u_3 - 1)$ and $L_{23} = (6u_1^2 - 3u_{1111})(u_3 - 1)$.

The corresponding multi-time Euler-Lagrange equations consist of a perturbed Boussinesq equation,

$$u_{22} = 12u_{11}u_{11} - 3u_{1111} + c$$
and
\[ u_3 = 1. \]

We have
\[ \frac{dL_{12}}{dt_3} - \frac{dL_{13}}{dt_2} + \frac{dL_{23}}{dt_1} = \epsilon \]
on solutions, hence \( dL \) is nonzero.

The multi-time Euler-Lagrange equations are equivalent to the canonical Hamiltonian systems with
\[ H_2 = \frac{1}{2} \pi^2 + 2u_1^3 + \frac{3}{2} u_{11}^2 - cu \]
\[ H_3 = \pi. \]

They are not in involution, but rather
\[ \{ \int H_2 \, dx, \int H_3 \, dx \} = \int (12u_{11}u_1 - 3u_{1111} + c) \, dx = \int c \, dx. \]

Note that if we would allow the fields in \( \mathcal{V} \) to depend explicitly on \( x \), then we would find \( \int c \, dx = \int \partial_x(cx) \, dx = 0 \). Note that this is not a property of the Lagrangian form, but of the function space we work in. Allowing fields that depend on \( x \) affects the definition of the formal integral \( \int (\cdot) \, dx \) as an equivalence class modulo \( x \)-derivatives. If dependence on \( x \) is allowed, then there is no such thing as a nonzero constant functional in this equivalence class. However, in our definition of \( \mathcal{V} \), fields can only depend on \( x \) through \( u \), hence \( c \) is not an \( x \)-derivative and \( \int c \, dx \) is not the zero element of \( \mathcal{F} \).

### 4.5 Additional (nonlocal) Poisson brackets

Even though the closedness property in Section 4.4 involves all coefficients of a Lagrangian 2-form \( \mathcal{L} \), so far we have only used the first row of coefficients \( \mathcal{L}_{1j} \) to construct Hamiltonian structures. A similar procedure can be carried out for other \( \mathcal{L}_{ij} \), but the results are not entirely satisfactory. In particular, it will not lead to true bi-Hamiltonian structures. Because of this slightly disappointing outcome, we will make no effort to present the most general statement possible. Instead we make some convenient assumptions on the form of the coefficients \( \mathcal{L}_{ij} \).

Consider a Lagrangian 2-form \( \mathcal{L} \) such that for all \( i < j \) the coefficient \( \mathcal{L}_{ij} \) only contains derivatives with respect to \( t_1, t_i \) and \( t_j \) (no “alien derivatives” in the terminology of [29]).

In addition, assume that \( \mathcal{L}_{ij} \) can be written as the sum of terms that each contain at most one derivative with respect to \( t_i \) (if \( i > 1 \)) or \( t_j \). In particular, \( \mathcal{L}_{ij} \) does not contain higher derivatives with respect to \( t_i \) (if \( i > 1 \)) or \( t_j \), but mixed derivatives with respect to \( t_1 \) and \( t_i \) or \( t_1 \) and \( t_j \) are allowed. There is no restriction on the amount of \( t_1 \)-derivatives.

To get a Hamiltonian description of the evolution along the time direction \( t_j \) from the Lagrangian \( \mathcal{L}_{ij} \), we should consider both \( t_1 \) and \( t_i \) as space coordinates. Hence we will work on the space
\[ \mathcal{V} / (\partial \mathcal{V} + \partial \mathcal{V}). \]
For $i > 1$, consider the momenta
\[ p^{[i]}[u] = \frac{\delta_1 L_{ij}}{\delta u_j}. \]

From the assumption that each term of $L_{ij}$ contains at most one time-derivative it follows that $p^{[i]}$ only depends on $u$ and its $x$-derivatives. Note that $p^{[i]}$ is independent of $j$ because of the multi-time Euler-Lagrange equation (6). The variational derivative in the definition of $p^{[i]}$ is in the directions $1$ and $i$, corresponding to the formal integral, whereas the Lagrangian coefficient has indices $i$ and $j$. However, we can also write
\[ p^{[i]}[u] = \frac{\delta_1 L_{ij}}{\delta u_j} \]
because of the assumption on the derivatives that occur in $L_{ij}$, which excludes mixed derivatives with respect to $t_i$ and $t_j$.

As Hamilton function we can take
\[ H_{ij} = p^{[i]} u_j - L_{ij}. \]

Its formal integral $\int H_{ij} \, dx \wedge dt_i$ does not depend on any $t_j$-derivatives. Since we are working with 2-dimensional integrals, we should take a $(2, 2)$-form as symplectic form. In analogy to Equation (13) we take
\[ \omega_i = -\delta p^{[i]} \wedge \delta u \wedge dx \wedge dt_i. \]

A Hamiltonian vector field $X = \chi \frac{\partial}{\partial u}$ satisfies
\[ \int i_X \omega_i = \int \delta H_{ij} \wedge dx \wedge dt_i \]
hence
\[ \mathcal{E}_{p^{[i]}} X = \frac{\delta_1 H_{ij}}{\delta u}, \]
where $\mathcal{E}_{p^{[i]}}$ is the differential operator
\[ \mathcal{E}_{p^{[i]}} = \sum_{k=0}^{\infty} \left( (-1)^k \partial_x^k \frac{\partial p^{[i]}}{\partial u_x} - \partial_x^k \frac{\partial p^{[i]}}{\partial u_x} \partial_x^k \right) \]

The corresponding (nonlocal) Poisson bracket is
\[ \left\{ \int f \, dx \wedge dt_i, \int g \, dx \wedge dt_i \right\}_i = - \int \frac{\delta_1 f}{\delta u} \mathcal{E}_{p^{[i]}}^{-1} \frac{\delta_1 g}{\delta u} \, dx \wedge dt_i. \]

Note that $H$ is not skew-symmetric, $H_{ij} \neq H_{ji}$.

The space of functionals $\mathcal{V}/(\partial_t \mathcal{V} + \partial \mathcal{V})$, on which the Poisson bracket $\{\cdot, \cdot\}_i$ is defined, depends on $i$ and is different from the space of functionals for the bracket $\{\cdot, \cdot\}$ from Equation (25). Hence no pair of these brackets are compatible with each other in the sense of a bi-Hamiltonian system.

As before, we can relate Poisson brackets between the Hamilton functionals to coefficients of $d\mathcal{L}$. 
Proposition 4.14. Assume that for all $i, j > 1$, $L_{ij}$ does not depend on any second or higher derivatives with respect to $t_i$ and $t_j$. On solutions of the Euler-Lagrange equations there holds that, for $i, j, k > 1$,

$$\int \left( \frac{dL_{ij}}{dt_k} - \frac{dL_{ik}}{dt_j} \right) dx \wedge dt_i = \int \left( p_j^{[i]} u_k - p_k^{[i]} u_j \right) dx \wedge dt_i = \left\{ \int H_{ij} dx \wedge dt_i, \int H_{ik} dx \wedge dt_i \right\}_i. \tag{28}$$

Proof. Analogous to the proof of Proposition 4.9. ■

Example 4.15. For the potential KdV equation (see Example 2.5) we have

$$p^{[2]} = \frac{\delta L_{23}}{\delta u_3} = \frac{3}{2} u_{111} + \frac{3}{2} u_1^2,$$

hence

$$\mathcal{E}_{p^{[2]}} = -\partial_1 \frac{\partial p^{[i]}_i}{\partial u_1} - \frac{\partial^2 p^{[i]}_i}{\partial u_{111}} - \frac{\partial p^{[i]}_i}{\partial u_{111}} \frac{\partial}{\partial u_1} - \frac{\partial p^{[i]}_i}{\partial u_{111}} \partial_1^3$$

$$= -3 \partial_1 u_1 - \frac{3}{2} \partial_1^3 - 3 u_1 \partial_1 - \frac{3}{2} \partial_1^3$$

$$= -3 \partial_1^3 - 6 u_1 \partial_1 - 3 u_1.$$

We have

$$H_{23} = p^{[2]} u_3 - L_{23}$$

$$= -3 u_1^5 + \frac{15}{2} u_1^2 u_{11} - 10 u_1^3 u_{111} + 5 u_1^3 u_3 - \frac{7}{2} u_{11}^2 u_{111} - 3 u_1 u_{111}^2 + 6 u_1 u_{111} u_{1111}$$

$$- \frac{3}{2} u_{111}^2 u_{11111} - 10 u_1 u_{11112} + \frac{5}{2} u_1^2 u_2 + \frac{5}{2} u_1 u_{111} u_2 + \frac{1}{2} u_{111}^2 - \frac{1}{2} u_{1111} u_{11111}$$

$$+ \frac{1}{2} u_{111} u_{112} - \frac{1}{2} u_1 u_{112} - u_{11111} u_{112} + \frac{1}{2} u_{1111} u_{13} + \frac{1}{2} u_{111111} u_2 + u_{1111} u_3,$$

where the terms involving $t_3$-derivatives cancel out when the Hamiltonian is integrated. Its variational derivative is

$$\frac{\delta_1 H_{23}}{\delta u} = 60 u_{111}^2 + 75 u_1^3 + 300 u_1 u_{111} u_{111} + 75 u_1^2 u_{11111} - 30 u_1^2 u_{12} - 30 u_1 u_{1111}$$

$$+ 120 u_{111} u_{11111} + 72 u_1 u_{111111} + 24 u_1 u_{111111} - 30 u_1 u_{11111} - 45 u_{11} u_{112}$$

$$- 25 u_{111} u_{12} - 5 u_{1111} u_2 + 2 u_{11111111} - 5 u_{1111111},$$

On solutions this simplifies to

$$\frac{\delta_1 H_{23}}{\delta u} = -210 u_1^3 u_{11} - 195 u_1^3 - 690 u_1 u_{111} u_{111} - 150 u_1^2 u_{11111} - 210 u_{111} u_{1111111}$$

$$- 123 u_{111} u_{1111111} - 3 u_{111111111}$$

$$= \mathcal{E}_{p^{[2]}} \left( 10 u_1^3 + 5 u_1^2 + 10 u_1 u_{111} + u_{11111} \right)$$

$$= \mathcal{E}_{p^{[2]}} u_3.$$
4.6 Comparison with the covariant approach

In Section 4.5 we derived Poisson brackets \{\cdot, \cdot\}_i, associated to each time variable \(t_i\). This was somewhat cumbersome because we had a priori assigned \(x = t_1\) as a distinguished variable. The recent work \([6]\) explores the relation of pluri-Lagrangian structures to covariant Hamiltonian structures. The meaning of “covariant” here is that all variables are on the same footing; there is no distinguished \(x\) variable. More details on covariant field theory, and its connection to the distinguished-variable (or “instantaneous”) perspective, can be found in \([13]\). The main objects in the covariant Hamiltonian formulation of \([6]\) are:

- A “symplectic multiform” \(\Omega\), which can be expanded as
  \[
  \Omega = \sum_j \omega_j \wedge dt_j,
  \]
  where each \(\omega_j\) is a vertical 2-form in the variational bicomplex.

- A “Hamiltonian multiform” \(\mathcal{H} = \sum_{i<j} H_{ij} dt_i \wedge dt_j\) which gives the equations of motion through
  \[
  \delta \mathcal{H} = \sum_j dt_j \wedge \xi_j \lrcorner \Omega,
  \]
  where \(\delta\) is the vertical exterior derivative in the variational bicomplex, \(\xi_j\) denotes the vector field corresponding to the \(t_j\)-flow, and \(\lrcorner\) denotes the interior product. This equation should be understood as a covariant version of the instantaneous Hamiltonian equation \(\delta H = \xi \lrcorner \omega\). On the equations of motion there holds \(d\mathcal{H} = 0\) if and only if \(dL = 0\).

Since the covariant Hamiltonian equation \((29)\) is of a different form than the instantaneous Hamiltonian equation we use, the coefficients \(H_{ij}\) of the Hamiltonian multiform \(\mathcal{H}\) are also different from the \(H_{ij}\) we found in Sections 4.3–4.5. Our \(H_{ij}\) are instantaneous Hamiltonians where \(t_1\) and \(t_i\) are considered as space variables and the Legendre transformation has been applied with respect to \(t_j\).

- A “multi-time Poisson bracket” \(!\cdot, \cdot!\) which defines a pairing between functions or (a certain type of) horizontal one-forms, defined by
  \[
  \{!F, G!\} = (-1)^r \xi_F \delta G,
  \]
  where \(\xi_F\) is the Hamiltonian (multi-)vector field associated to \(F\), and \(r\) is the horizontal degree of \(F\) (which is either 0 or 1). The equations of motion can be written as
  \[
  dF = \sum_{i<j} \{!H_{ij}, F!\} dt_i \wedge dt_j.
  \]

Single-time Poisson brackets are obtained in \([6]\) by expanding the multi-time Poisson bracket as
\[
\left\{ \left| \sum_j F_j dt_j, \sum_j G_j dt_j \right| \right\} = \sum_j \{F_j, G_j\}_j dt_j
\]
where
\[
\{ f, g \}_j = -\xi^\omega_{j,\cdot} \delta g \quad \text{and} \quad \xi^\omega_{j,\cdot} \omega_j = \delta f. \tag{30}
\]
These are fundamentally different from the Poisson brackets of Sections 4.3–4.5 because they act on different function spaces. Equation (30) assumes that \( \delta f \) lies in the image of \( \omega_j \) (considered as a map from vertical vector fields to vertical one-forms). For example, for the potential KdV hierarchy one has \( \omega_1 = \delta v \wedge \delta v_1 \), hence the Poisson bracket \( \{ \cdot, \cdot \}_1 \) can only be applied to functions of \( v \) and \( v_1 \), not to functions depending on any higher derivatives. Similar conditions on the function space apply to the higher Poisson brackets corresponding to \( \omega_j, j \geq 2 \). On the other hand, the Poisson brackets of Sections 4.3–4.5 are defined on an equivalence class of functions modulo certain derivatives, without further restrictions on the functions in this class.

In summary, the single-time Poisson brackets of [6] are constructed with a certain elegance in a covariant way, but they are defined only in a restricted function space. They are different from our Poisson brackets of Section 4.3–4.5 which have no such restrictions, but break covariance already in the definition of the function space as an equivalence class. It is not clear how to pass from one picture to the other, or if their respective benefits can be combined into a single approach.

5 Conclusions

We have established a connection between pluri-Lagrangian systems and integrable Hamiltonian hierarchies. In the case of ODEs, where the pluri-Lagrangian structure is a 1-form, this connection was already obtained in [26]. Our main contribution is its generalization to the case of 2-dimensional PDEs, described by Lagrangian 2-forms. Presumably, this approach extends to Lagrangian \( d \)-forms of any dimension \( d \), but the details of this are postponed to future work.

A central property in the theory of pluri-Lagrangian systems is that the Lagrangian form is (almost) closed on solutions. We showed that closedness is equivalent to the corresponding Hamilton functions being in involution.

Although one can obtain several Poisson brackets (and corresponding Hamilton functions) from one Lagrangian 2-form, these do not form a bi-Hamiltonian structure and it is not clear if a recursion operator can be obtained from them. Hence it remains an open question to find a fully variational description of bi-Hamiltonian hierarchies.

A  Pluri-Lagrangian systems and the variational bicomplex

In this appendix we study the pluri-Lagrangian principle using the variational bicomplex, described in Section 4.1. We provide proofs that the multi-time Euler-Lagrange equations from Section 2 are sufficient conditions for criticality. Alternative proofs of this fact can be found in [28] and [23, Appendix A].

**Proposition A.1.** The field $u$ is a solution to the pluri-Lagrangian problem of a $d$-form $L[u]$ if locally there exists a $(1,d-1)$-form $\Theta$ such that $\delta L[u] = d\Theta$.

**Proof.** Consider a field $u$ such that such a $(1,d-1)$-form $\Theta$ exists. Consider any $d$-manifold $\Gamma$ and any variation $v$ that vanishes (along with all its derivatives) on the boundary $\partial \Gamma$. Note that the horizontal exterior derivative $d$ anti-commutes with the interior product operator $\iota_V$, where $V$ is the prolonged vertical vector field $V = \text{pr}(v \partial/\partial u)$ defined by the variation $v$. It follows that

$$\int_\Gamma \iota_V \delta L = -\int_\Gamma d(\iota_V \Theta) = -\int_{\partial \Gamma} \iota_V \Theta = 0,$$

hence $u$ solves the pluri-Lagrangian problem.  

If we are dealing with a classical Lagrangian problem from mechanics, $L = L(u, u_t) \, dt$, we have $\Theta = -\partial L/\partial u_t \delta u$, which is the pull back to the tangent bundle of the canonical 1-form $\sum_i p_i \, dq_i$ on the cotangent bundle.

Often we want the Lagrangian form to be closed when evaluated on solutions. As we saw in Theorems 3.7 and 4.11 this implies that the corresponding Hamiltonians are in involution. We did not include this in the definition of a pluri-Lagrangian system, because our definition already implies a slightly weaker property.

**Proposition A.2.** The horizontal exterior derivative $dL$ of a pluri-Lagrangian form is constant on connected components of the set of critical fields for $L$.

**Proof.** Critical points satisfy locally

$$\delta L = d\Theta \quad \Rightarrow \quad d\delta L = 0 \quad \Rightarrow \quad \delta dL = 0.$$

Hence for any variation $v$ the Lie derivative of $dL$ along its prolongation $V = \text{pr}(v \partial/\partial u)$ is $\iota_V \delta (dL) = 0$. Therefore, if a solution $u$ can be continuously deformed into another solution $\bar{u}$, then $dL[u] = dL[\bar{u}]$.

Now let us prove the sufficiency of the multi-time Euler-Lagrange equations for 1-forms and 2-forms, as given in Theorems 2.2 and 2.4. For different approaches to the multi-time Euler-Lagrange equations, including proofs of necessity, see [28] and [23].

**Proof of sufficiency in Theorem 2.2.** We calculate the vertical exterior derivative $\delta L$ of the Lagrangian 1-form, modulo the multi-time Euler-Lagrange Equations (1) and (2). We have

$$\delta L = \sum_{j=1}^N \sum_I \frac{\partial L_j}{\partial u_I} \delta u_I \wedge dt_j$$

$$= \sum_{j=1}^N \sum_I \left( \frac{\delta_j L_j}{\partial u_I} + \partial_j \frac{\delta_j L_j}{\partial u_{It_j}} \right) \delta u_I \wedge dt_j.$$
Rearranging this sum, we find
\[ \delta L = \sum_{j=1}^{N} \left[ \sum_{l \neq t_j} \frac{\partial L_j}{\partial u_l} \delta u_l \wedge dt_j + \sum_{I} \left( \frac{\partial_j L_j}{\delta u_{I_{t_j}}} \delta u_{I_{t_j}} \wedge dt_j + \left( \partial_j \frac{\partial_j L_j}{\delta u_{I_{t_j}}} \right) \delta u_I \wedge dt_J \right) \right]. \]

On solutions of Equation (2), we can define the generalized momenta
\[ p^I = \frac{\partial_j L_j}{\delta u_{I_{t_j}}}. \]

Using Equations (1) and (2) it follows that
\[ \delta L = \sum_{j=1}^{N} \sum_{I} \left( \frac{p^I}{\delta u_{I_{t_j}}} \wedge dt_j + \left( \partial_j \frac{\partial_j L_j}{\delta u_{I_{t_j}}} \right) \delta u_I \wedge dt_J \right) = -d \left( \sum_I p^I \delta u_I \right). \]

This implies by Proposition A.1 that \( u \) solves the pluri-Lagrangian problem. \( \square \)

**Proof of sufficiency in Theorem 2.4.** We calculate the vertical exterior derivative \( \delta L \),
\[ \delta L = \sum_{i<j} \sum_{I} \frac{\partial L_{ij}}{\partial u_I} \delta u_I \wedge dt_i \wedge dt_j \]
\[ = \sum_{i<j} \sum_{I} \left( \frac{\partial_i L_{ij}}{\partial u_I} + \frac{\partial_j L_{ij}}{\partial u_I} + \partial_i \partial_j L_{ij} \right) \delta u_I \wedge dt_i \wedge dt_j \]
(31)

We will rearrange this sum according to the times occurring in the multi-index \( I \). We have
\[ \sum_I \frac{\partial_i L_{ij}}{\delta u_I} \delta u_I = \sum_{I \neq t_i} \frac{\partial_i L_{ij}}{\delta u_I} \delta u_I + \sum_{I \neq t_{I_{t_j}}} \frac{\partial_i L_{ij}}{\delta u_{I_{t_j}}} \delta u_{I_{t_j}} \]
\[ + \sum_{I \neq t_{I_{t_j}}} \frac{\partial_i L_{ij}}{\delta u_{I_{t_j}}} \delta u_{I_{t_j}} \sum_{I \neq t_{I_{t_j}}} \frac{\partial_i L_{ij}}{\delta u_{I_{t_j}}} \delta u_{I_{t_j}}, \]
\[ \sum_I \frac{\partial_i L_{ij}}{\delta u_I} \delta u_I = \sum_{I \neq t_i} \frac{\partial_i L_{ij}}{\delta u_I} \delta u_I + \sum_{I \neq t_{I_{t_j}}} \frac{\partial_i L_{ij}}{\delta u_{I_{t_j}}} \delta u_{I_{t_j}}, \]
\[ \sum_I \frac{\partial_i L_{ij}}{\delta u_I} \delta u_I = \sum_{I \neq t_i} \frac{\partial_i L_{ij}}{\delta u_I} \delta u_I + \sum_{I \neq t_{I_{t_j}}} \frac{\partial_i L_{ij}}{\delta u_{I_{t_j}}} \delta u_{I_{t_j}}. \]

Modulo the multi-time Euler-Lagrange equations (5)–(7), we can write these expressions as
\[ \sum_I \frac{\partial_i L_{ij}}{\delta u_I} \delta u_I = \sum_{I \neq t_i} p^I \delta u_{I_{t_i}} - \sum_{I \neq t_{I_{t_j}}} p^I \delta u_{I_{t_j}} + \sum_I (n^I_j - n^I_t) \delta u_{I_{t_j}}, \]
\[ \sum_I \frac{\partial_i L_{ij}}{\delta u_I} \delta u_I = \sum_{I \neq t_i} \partial_i p^I \delta u_I + \sum_I \partial_i (n_j^I - n_t^I) \delta u_{I_{t_j}}, \]
\[ \sum_I \frac{\partial_i L_{ij}}{\delta u_I} \delta u_I = \sum_{I \neq t_i} -\partial_j p^I \delta u_I + \sum_I \partial_j (n_j^I - n_t^I) \delta u_{I_{t_j}}, \]
\[ \sum_I \frac{\partial_i L_{ij}}{\delta u_{I_{t_j}}} \delta u_I = \sum_I \partial_i \partial_j (n_j^I - n_t^I) \delta u_I. \]
where
\[ p^I_j = \frac{\delta L_{1j}}{\delta u_{I_1}}, \quad \text{for } I \notin t_j, \]
\[ n^I_j = \frac{\delta L_{1j}}{\delta u_{I_1}t_j}. \]

Note that here the indices of \( p \) and \( n \) are labels, not derivatives. Hence on solutions to equations (5)–(7), Equation (31) is equivalent to
\[
\delta L = \sum_{i < j} \left[ \sum_{I \notin t_j} (p^I_j \delta u_{I_1} + \partial_i p^I_j \delta u_I) - \sum_{I \notin t_i} (p^I_i \delta u_{I_1} + \partial_j p^I_i \delta u_I) \right] \\
+ \sum_I \left( (n^I_j - n^I_i) \delta u_{I_1} + \partial_j (n^I_j - n^I_i) \delta u_{I_1} \right) \\
+ \partial_i (n^I_j - n^I_i) \delta u_{I_1} + \partial_i \partial_j (n^I_j - n^I_i) \delta u_I \right] \wedge dt_i \wedge dt_j.
\]

Using the anti-symmetry of the wedge product, we can write this as
\[
\delta L = \sum_{i, j=1}^N \left[ \sum_{I \notin t_j} (p^I_j \delta u_{I_1} + \partial_i p^I_j \delta u_I) \right] \\
+ \sum_I \left( n^I_j \delta u_{I_1} + \partial_j n^I_j \delta u_{I_1} + \partial_i n^I_j \delta u_{I_1} + \partial_i \partial_j n^I_j \delta u_I \right] \wedge dt_i \wedge dt_j \\
= \sum_{j=1}^N \left[ \sum_{I \notin t_j} -d (p^I_j \delta u_I \wedge dt_j) + \sum_I -d (n^I_j \delta u_{I_1} \wedge dt_j + \partial_j n^I_j \delta u_I \wedge dt_j) \right].
\]

It now follows by Proposition A.1 that \( u \) is a critical field.
